

Lecture 13

Outline:

- Amdahl's law
- Speed up, strong and weak scaling
- OpenMP

Amdahl's Law

Typically only part of a computation can be parallelized.

Suppose 50% of the computation is inherently sequential,
and the other 50% can be parallelized.

Question: How much faster could the computation potentially run on many processors?

Amdahl's Law

Typically only part of a computation can be parallelized.

Suppose 50% of the computation is inherently sequential, and the other 50% can be parallelized.

Question: How much faster could the computation potentially run on many processors?

Answer: At most a factor of 2, no matter how many processors.

The sequential part is taking half the time and that time is still required even if the parallel part is reduced to zero time.

Amdahl's Law

Suppose 10% of the computation is inherently sequential,
and the other 90% can be parallelized.

Question: How much faster could the computation potentially
run on many processors?

Amdahl's Law

Suppose 10% of the computation is inherently sequential, and the other 90% can be parallelized.

Question: How much faster could the computation potentially run on many processors?

Answer: At most a factor of 10, no matter how many processors.

The sequential part is taking $1/10$ of the time and that time is still required even if the parallel part is reduced to zero time.

Amdahl's Law

Suppose $1/S$ of the computation is inherently sequential,
and the other $(1 - 1/S)$ can be parallelized.

Then can gain at most a factor of S , no matter how many
processors.

Amdahl's Law

Suppose $1/S$ of the computation is inherently sequential, and the other $(1 - 1/S)$ can be parallelized.

Then can gain at most a factor of S , no matter how many processors.

If T_S is the time required on a sequential machine and we run on P processors, then the time required will be (at least):

$$T_P = (1/S)T_S + (1 - 1/S)T_S/P$$

Amdahl's Law

Suppose $1/S$ of the computation is inherently sequential, and the other $(1 - 1/S)$ can be parallelized.

Then can gain at most a factor of S , no matter how many processors.

If T_S is the time required on a sequential machine and we run on P processors, then the time required will be (at least):

$$T_P = (1/S)T_S + (1 - 1/S)T_S/P$$

Note that

$$T_P \rightarrow (1/S)T_S \quad \text{as } P \rightarrow \infty$$

Amdahl's Law

Suppose $1/S$ of the computation is inherently sequential \Rightarrow

$$T_P = (1/S)T_S + (1 - 1/S)T_S/P$$

Example: If 5% of the computation is inherently sequential ($S = 20$), then the reduction in time is:

P	T_P
1	T_S
2	$0.525T_S$
4	$0.288T_S$
32	$0.080T_S$
128	$0.057T_S$
1024	$0.051T_S$

Speedup

The ratio T_S/T_P of time on a sequential machine to time running in parallel is the **speedup**.

This is generally less than P for P processors.
Perhaps much less.

Amdahl's Law plus overhead costs of starting processes/threads, communication, etc.

Speedup

The ratio T_S/T_P of time on a sequential machine to time running in parallel is the **speedup**.

This is generally less than P for P processors.
Perhaps much less.

Amdahl's Law plus overhead costs of starting processes/threads, communication, etc.

Caveat: May (rarely) see speedup greater than P ...
For example, if data doesn't all fit in one cache
but does fit in the combined caches of multiple processors.

Scaling

Some algorithms **scale** better than others as the number of processors increases.

Typically interested on how well algorithms work for large problems requiring lots of time, e.g.

- Particle methods for n particles,
- algorithms for solving systems of n equations,
- algorithms for solving PDEs on $n \times n \times n$ grid in 3D,

Scaling

Some algorithms **scale** better than others as the number of processors increases.

Typically interested on how well algorithms work for large problems requiring lots of time, e.g.

- Particle methods for n particles,
- algorithms for solving systems of n equations,
- algorithms for solving PDEs on $n \times n \times n$ grid in 3D,

For large n , there **may** be lots of inherent parallelism.

But this depends on many factors:

- dependencies between calculations,
- communication as well as flops,
- nature of problem and algorithm chosen.

Scaling

Typically interested on how well algorithms work for large problems requiring lots of time.

Strong scaling: How does the algorithm perform as the number of processors P increases for a **fixed problem size n** ?

Any algorithm will eventually break down (consider $P > n$)

Scaling

Typically interested on how well algorithms work for large problems requiring lots of time.

Strong scaling: How does the algorithm perform as the number of processors P increases for a **fixed problem size n** ?

Any algorithm will eventually break down (consider $P > n$)

Weak scaling: How does the algorithm perform when the problem size increases with the number of processors?

E.g. If we double the number of processors can we solve a problem “twice as large” in the same time?

Weak scaling

What does “twice as large” mean?

Depends on how algorithm complexity scales with n .

Example: Solving $n \times n$ linear system with Gaussian elimination requires $O(n^3)$ flops.

Doubling n requires 8 times as many operations.

Weak scaling

What does “twice as large” mean?

Depends on how algorithm complexity scales with n .

Example: Solving $n \times n$ linear system with Gaussian elimination requires $O(n^3)$ flops.

Doubling n requires 8 times as many operations.

Problem is “twice as large” if we increase n by a factor of $2^{1/3} \approx 1.26$, e.g. from 100×100 to 126×126 .

Weak scaling

What does “twice as large” mean?

Depends on how algorithm complexity scales with n .

Example: Solving $n \times n$ linear system with Gaussian elimination requires $O(n^3)$ flops.

Doubling n requires 8 times as many operations.

Problem is “twice as large” if we increase n by a factor of $2^{1/3} \approx 1.26$, e.g. from 100×100 to 126×126 .

(Or may be better to count memory accesses!)

Weak scaling

Solving steady state heat equation on $n \times n \times n$ grid.

n^3 grid points \Rightarrow linear system with this many unknowns.

If we used Gaussian elimination (very bad idea!) we would require $\sim (n^3)^3 = n^9$ flops.

Doubling n would require $2^9 = 512$ times more flops.

Weak scaling

Solving steady state heat equation on $n \times n \times n$ grid.

n^3 grid points \Rightarrow linear system with this many unknowns.

If we used Gaussian elimination (very bad idea!) we would require $\sim (n^3)^3 = n^9$ flops.

Doubling n would require $2^9 = 512$ times more flops.

Good iterative methods can do the job in $O(n^3) \log_2(n)$ work or less. (e.g. multigrid).

Weak scaling

Solving steady state heat equation on $n \times n \times n$ grid.

n^3 grid points \Rightarrow linear system with this many unknowns.

If we used Gaussian elimination (very bad idea!) we would require $\sim (n^3)^3 = n^9$ flops.

Doubling n would require $2^9 = 512$ times more flops.

Good iterative methods can do the job in $O(n^3) \log_2(n)$ work or less. (e.g. multigrid).

Developing better algorithms is as important as better hardware!!

Speedup for problems like steady state heat equation

“Open Specifications for MultiProcessing”

Standard for shared memory parallel programming.
For shared memory computers, such as multi-core.

Can be used with Fortran (77/90/95/2003), C and C++.

Complete specifications at <http://www.openmp.org>

OpenMP — Basic Idea

Explicit programmer control of parallelization using fork-join model of parallel execution

- all OpenMP programs begin as single process, the master thread, which executes until a parallel region construct encountered
- FORK: master thread creates team of parallel threads
- JOIN: When threads complete statements in parallel region construct they synchronize and terminate, leaving only the master thread.

OpenMP — Basic Idea

- **Rule of thumb:** One thread per processor (or core),
- User inserts **compiler directives** telling compiler how statements are to be executed
 - which parts are parallel
 - how to assign code in **parallel regions** to threads
 - what data is **private** (local) to threads
- Compiler generates explicit threaded code

OpenMP — Basic Idea

- **Rule of thumb:** One thread per processor (or core),
- User inserts **compiler directives** telling compiler how statements are to be executed
 - which parts are parallel
 - how to assign code in **parallel regions** to threads
 - what data is **private** (local) to threads
- Compiler generates explicit threaded code
- **Dependencies** in parallel parts require **synchronization** between threads
- User's job to **remove dependencies** in parallel parts or use **synchronization**. (Tools exist to look for **race conditions**.)

OpenMP compiler directives

Uses **compiler directives** that start with `!$` (pragmas in C.)

These look like comments to standard Fortran but are recognized when compiled with the flag `-fopenmp`.

OpenMP statements:

Ordinary Fortran statements conditionally compiled:

```
!$ print *, "Compiled with -fopenmp"
```

OpenMP compiler directives, e.g.

```
!$omp parallel do
```

Calls to OpenMP library routines:

```
use omp_lib      ! need this module
!$ call omp_set_num_threads(2)
```

OpenMP directives

```
!$omp directive  [clause ...]  
                  if (scalar_expression)  
                  private (list)  
                  shared (list)  
                  default (shared | none)  
                  firstprivate (list)  
                  reduction (operator: list)  
                  copyin (list)  
                  num_threads (integer-expression)
```

A few OpenMP directives

```
!$omp parallel [clause]  
    ! block of code  
!$omp end parallel
```

```
!$omp parallel do [clause]  
    ! do loop  
!$omp end parallel do
```

```
!$omp barrier  
    ! wait until all threads arrive
```

Several others we'll see later...

API also provides for (but implementation may not support):

- Nested parallelism (parallel constructs inside other parallel constructs)
- Dynamically altering number of threads in different parallel regions

The standard says nothing about parallel I/O.

OpenMP provides "relaxed-consistency" view of memory.

Threads can cache their data and are not required to maintain exact consistency with real memory all the time.

```
!$omp flush
```

can be used as a **memory fence** at a point where all threads must have consistent view of memory.

OpenMP test code

```
program test
  use omp_lib
  integer :: thread_num

  ! Specify number of threads to use:
  !$ call omp_set_num_threads(2)

  print *, "Testing openmp ..."

  !$omp parallel
  !$omp critical
  !$ thread_num = omp_get_thread_num()
  !$ print *, "This thread = ",thread_num
  !$omp end critical
  !$omp end parallel
end program test
```

OpenMP test code output

Compiled with OpenMP:

```
$ gfortran -fopenmp test.f90
```

```
$ ./a.out
```

```
Testing openmp ...
```

```
This thread = 0
```

```
This thread = 1
```

(or threads might print in the other order!)

Compiled without OpenMP:

```
$ gfortran test.f90
```

```
$ ./a.out
```

```
Testing openmp ...
```

OpenMP test code

```
! Specify number of threads to use:  
!$ call omp_set_num_threads(2)
```

Can specify more threads than processors, but they won't execute in parallel.

The number of threads is determined by (in order):

- Evaluation of **if** clause of a directive
(if evaluates to zero or false \Rightarrow serial execution)
- Setting the **num_threads** clause
- the **omp_set_num_threads()** library subroutine
- the **OMP_NUM_THREADS** environment variable
- Implementation default

OpenMP test code

```
!$omp parallel
!$omp critical
!$ thread_num = omp_get_thread_num()
!$ print *, "This thread = ",thread_num
!$omp end critical
!$omp end parallel
```

The `!$omp parallel` block **spawns two threads** and each one works independently, doing all instructions in block.

Threads are destroyed at `!$omp end parallel`.

However, the statements are also in a `!$omp critical` block, which indicates that this section of the code can be executed by only one thread at a time, so in fact they are not done in parallel.

So why do this? The function `omp_get_thread_num()` returns a unique number for each thread and we want to print both of these.

OpenMP test code

Incorrect code without critical section:

```
!$omp parallel
!$ thread_num = omp_get_thread_num()
!$ print *, "This thread = ", thread_num
!$omp end parallel
```

Why not do these in parallel?

1. If the prints are done simultaneously they may come out **garbled** (characters of one interspersed in the other).
2. `thread_num` is a **shared variable**. If this were not in a critical section, the following would be possible:

```
Thread 0 executes function, sets thread_num=0
Thread 1 executes function, sets thread_num=1
Thread 0 executes print statement: "This thread = 1"
Thread 1 executes print statement: "This thread = 1"
```

There is a **data race** or **race condition**.

OpenMP test code

Could change to add a **private** clause:

```
!$omp parallel private(thread_num)

!$ thread_num = omp_get_thread_num()

!$omp critical
!$ print *, "This thread = ",thread_num
!$omp end critical
!$omp end parallel
```

Then each thread has it's own version of the `thread_num` variable.
